Assignmnet 23 Solutions

1. What is the result of the code, and why?

```
>>> def function(a, b=6, c=8):
print(a, b, c)
>>> func(1, 2)
```

ANS: The result of the above code is 1 2 8.its because the function uses the default value of c ie 8 which is provided at the time of declaration

```
In [1]:
    def func(a,b=6,c=8):
        print(a,b,c)
    func(1,2)
```

2. What is the result of this code, and why?

```
>>> def func(a, b, c=5):
print(a, b, c)
>>> func(1, c=3, b=2)
```

ANS: The result of the above code is **1 2 3**.it is because the function will use default values only when a value for a argument is not provided and if argument name is mentioned while doing a function call, the order of arguments is also igored by the python interpreter

```
In [2]: def func(a,b,c=5):
    print(a,b,c)
func(1,c=3,b=2)
```

1 2 3

3. How about this code: what is its result, and why?

```
>>> def func(a, *pargs):
print(a, pargs )
>>> func(1, 2, 3)
```

ANS: The result of the code is **1 (2,3).** pargs** stands for variable length arguments. this format is used when we are not sure about the no of arguments to be passed to a function.all the values under this argument will be stored in a tuple.

```
In [4]:
    def func(a, *pargs):
        print(a,pargs)
    func(1,2,3)

1 (2, 3)
```

4. What does this code print, and why?

```
>>> def func(a, kargs):

print(a, kargs)

**>>> func(a=1, c=3, b=2)
```

ANS: The result of the above code is 1 {'c': 3, 'b': 2}. **args stands for variable length keyword arguments.this format is used when we want pass key value pairs as input to a function. All these key value pairs will be stored in a dictionary

```
In [5]: def func(a,**kargs):
    print(a,kargs)
    func(a=1,c=3,b=2)

1 {'c': 3, 'b': 2}
```

5. What gets printed by this, and explain?

```
>>> def func(a, b, c=8, d=5): print(a, b, c, d)
>>> func(1, *(5, 6) )
```

ANS: The output of the above is 1 5 6 5. This reason for this function not throwing an error is because, this function expects 4 arguments. the value for a is provided explicitly whereas for arguments b and c, the function will expand the *(5,6) and consider the value of b as 5 and value of c as 6. since the default value of d is provided in function declaration d value will be 5. However it is recommended to use the feature of positional arguments at the end.

```
In [6]:
    def func(a,b,c=8,d=5):
        print(a,b,c,d)
    func(1,*(5,6))

1 5 6 5
```

6. what is the result of this, and explain?

```
>>> def func(a, b, c): a = 2; b[0] = 'x'; c['a'] = 'y'
>>> l=1; m=[1]; n={'a':0}
>>> func(l, m, n)
>>> l, m, n
```

ANS: The output of above code is 1, ['x'], {'a': 'y'}

- 1. Eventhough Python gives importance to indentation.its provides a facility to declare an entire function in one single line.where statements in a function body are sepereated by;
- 2. When I,m,n are provided as inputs to the function.its modifies the values of I,m,n and sets the value of I=2,m=['x'] and n={'a':'y'}

```
In [7]:
    def func(a, b, c): a = 2; b[0] = 'x'; c['a'] = 'y'
    l=1; m=[1]; n={'a':0}
    func(l, m, n)
    l,m,n
Out[7]: (1, ['x'], {'a': 'y'})
```
